

# Computer modelling of dimensional response and stress fields in wooden artworks

---

Lukasz Bratasz, Bartosz Rachwal

# Aim

---

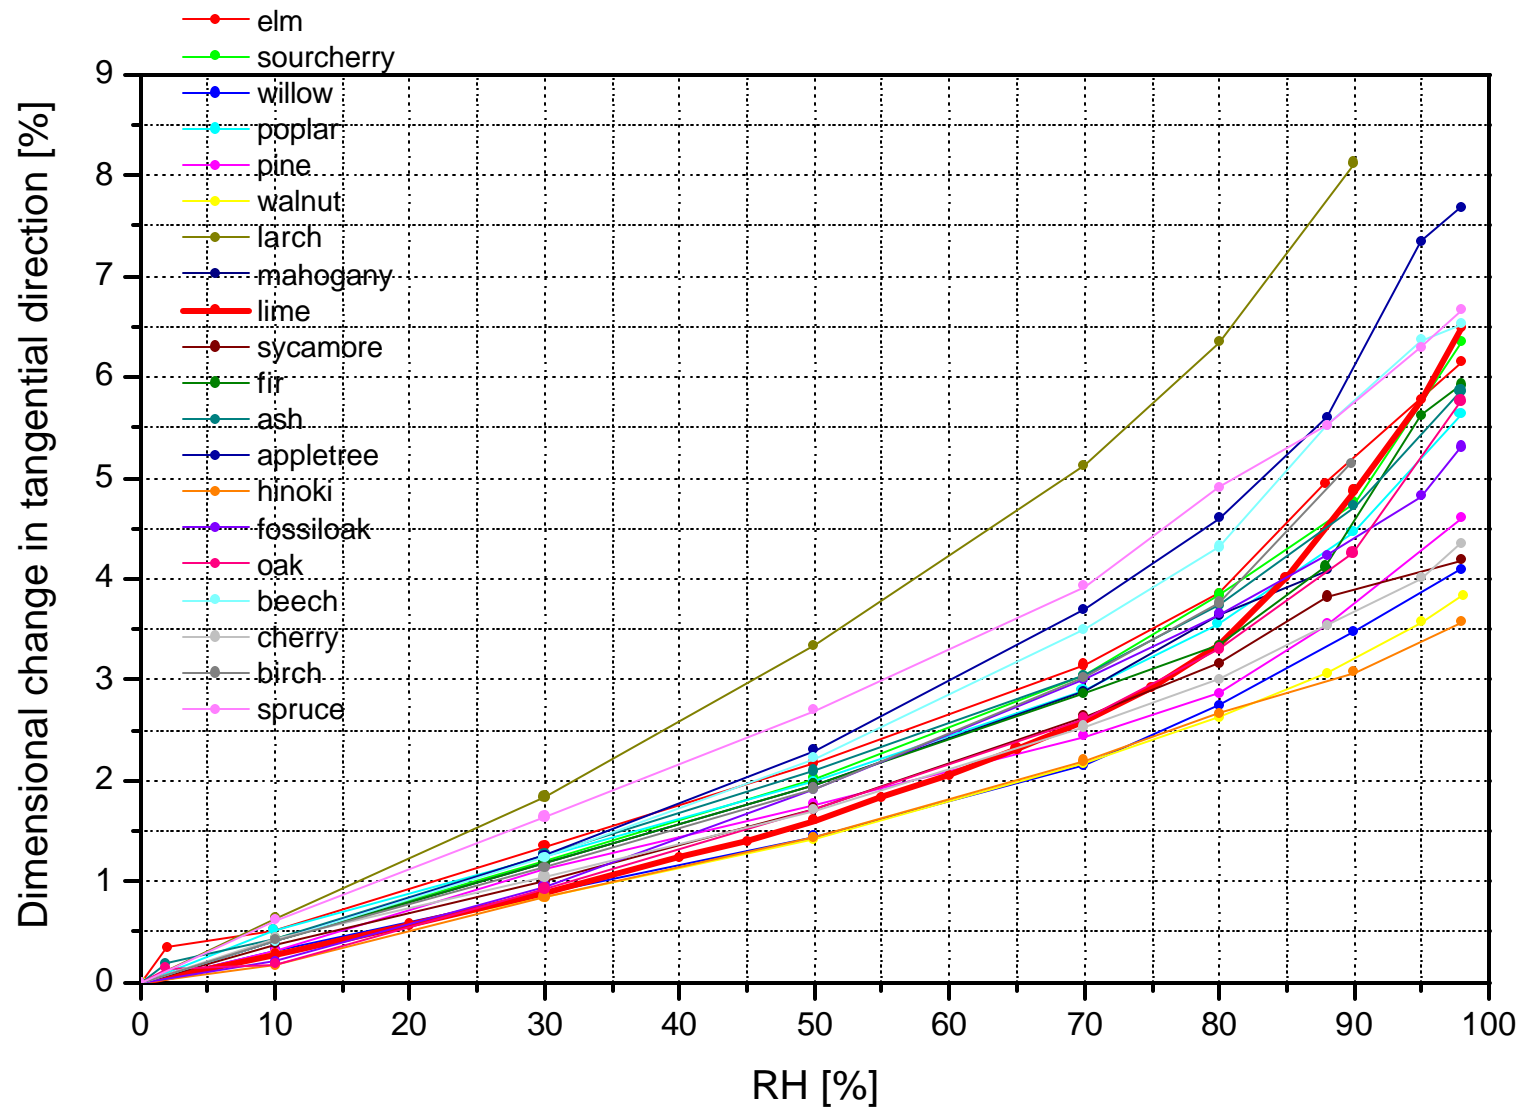

To translate critical strain values determined in the fatigue tests into **allowable RH variations**

# Cumulative crack length in the decorative layer vs number of strain cycles

---

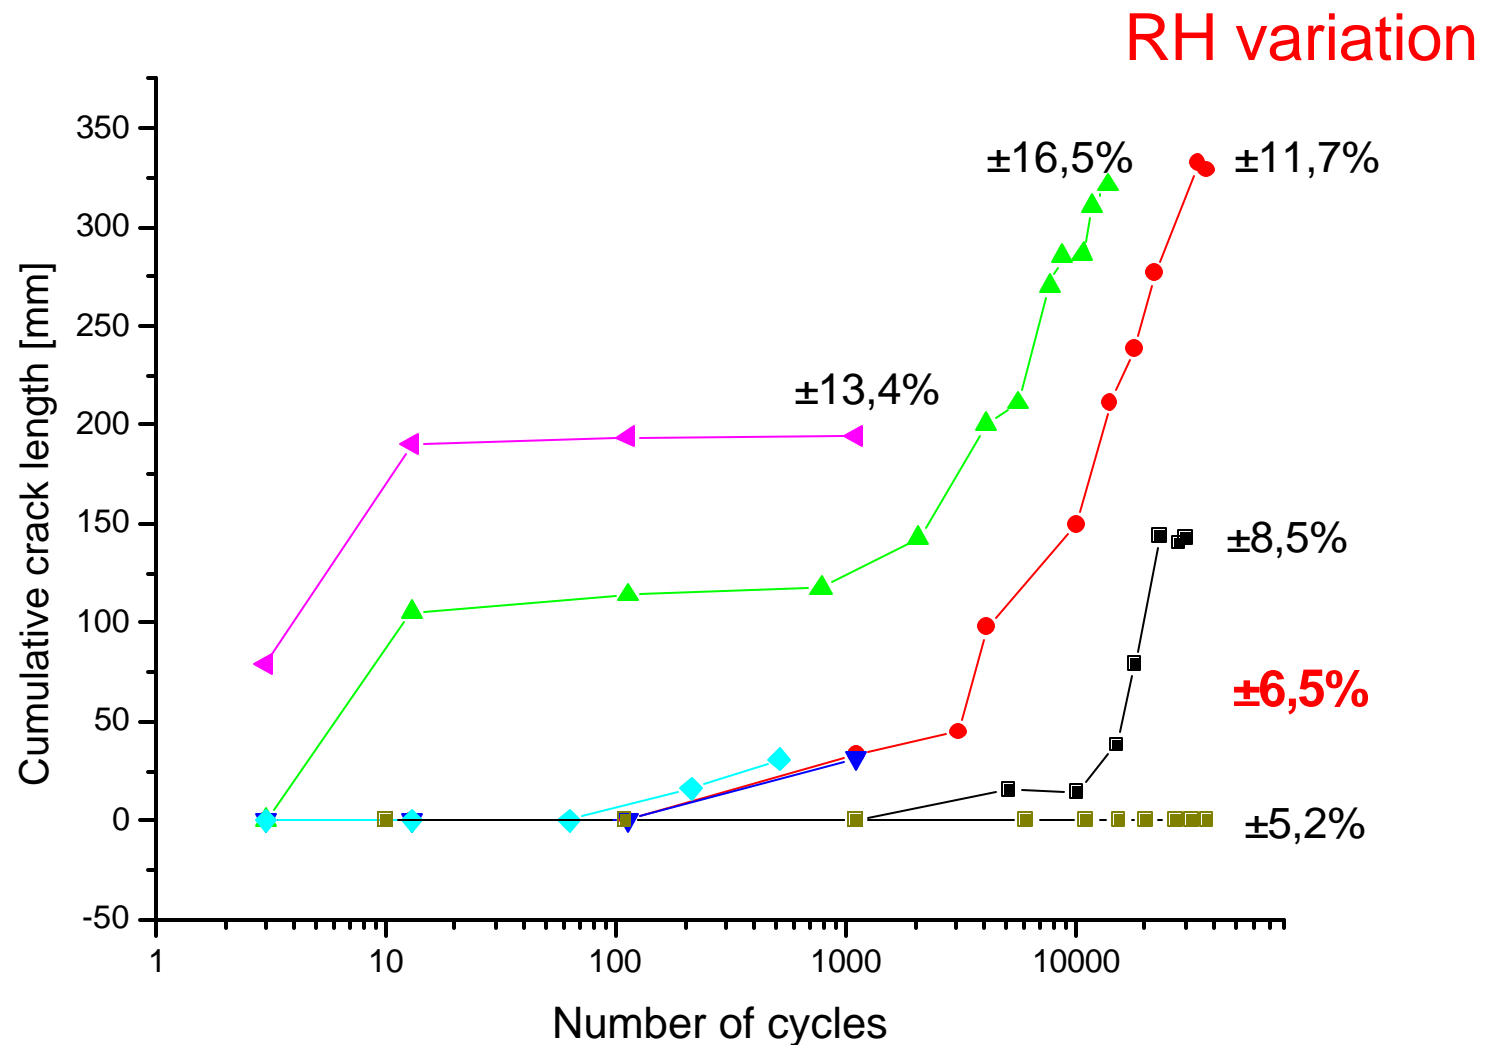

RH variation for a given strain is calculated from  
the swelling isotherm - lime wood is typical

---

# RH variations centred at 50%rh corresponding to the mismatch between wood and gesso

# Amplitude of the RH variation vs number of cycles after which damage appears

---

# The first step approximating the allowable RH variations

---

- RH-induced wood movement causing strain in the gesso layer of around 0.2% corresponds to a very narrow variation of  $\pm 6.5\%rh$  centred at 50%rh for lime wood in the tangential direction
- further effects need to be taken into account

# Further effects

---

The safe range of RH variations is broader due to several phenomena:

- **hysteresis** in swelling/shrinkage
- **slow response** of wood to short-term variations in RH
- ability of the panels to **deform**

# Hysteresis loop between the swelling/shrinkage isotherm for lime-wood

---

# Strain reduction due to the hysteresis

reduction of strain for various RH changes  
centred at 30%, 50% and 70% RH is  
approximately 25%

# Amplitude of the allowable RH variation vs number of cycles - a correction due to the hysteresis

---

# Slow response of wood to short-term variations in RH

Poplar panel 4 cm thick, RH 63 → 45 → 65%

P.D. Vici, P. Mazzanti, L. Uzielli, *J. Cult. Her.* 7 (2006) 37-48

# Diffusion of moisture into wood

Time needed to achieve 63% of the final EMC in a panel with both faces free to exchange moisture, subjected to a step RH change

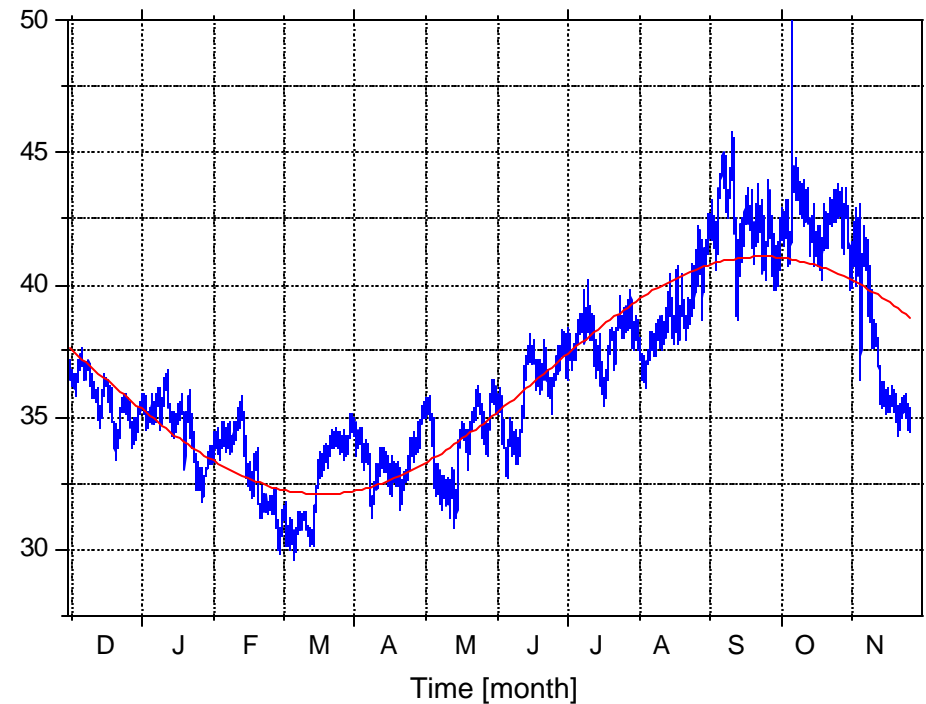

# RH variations have various time scales

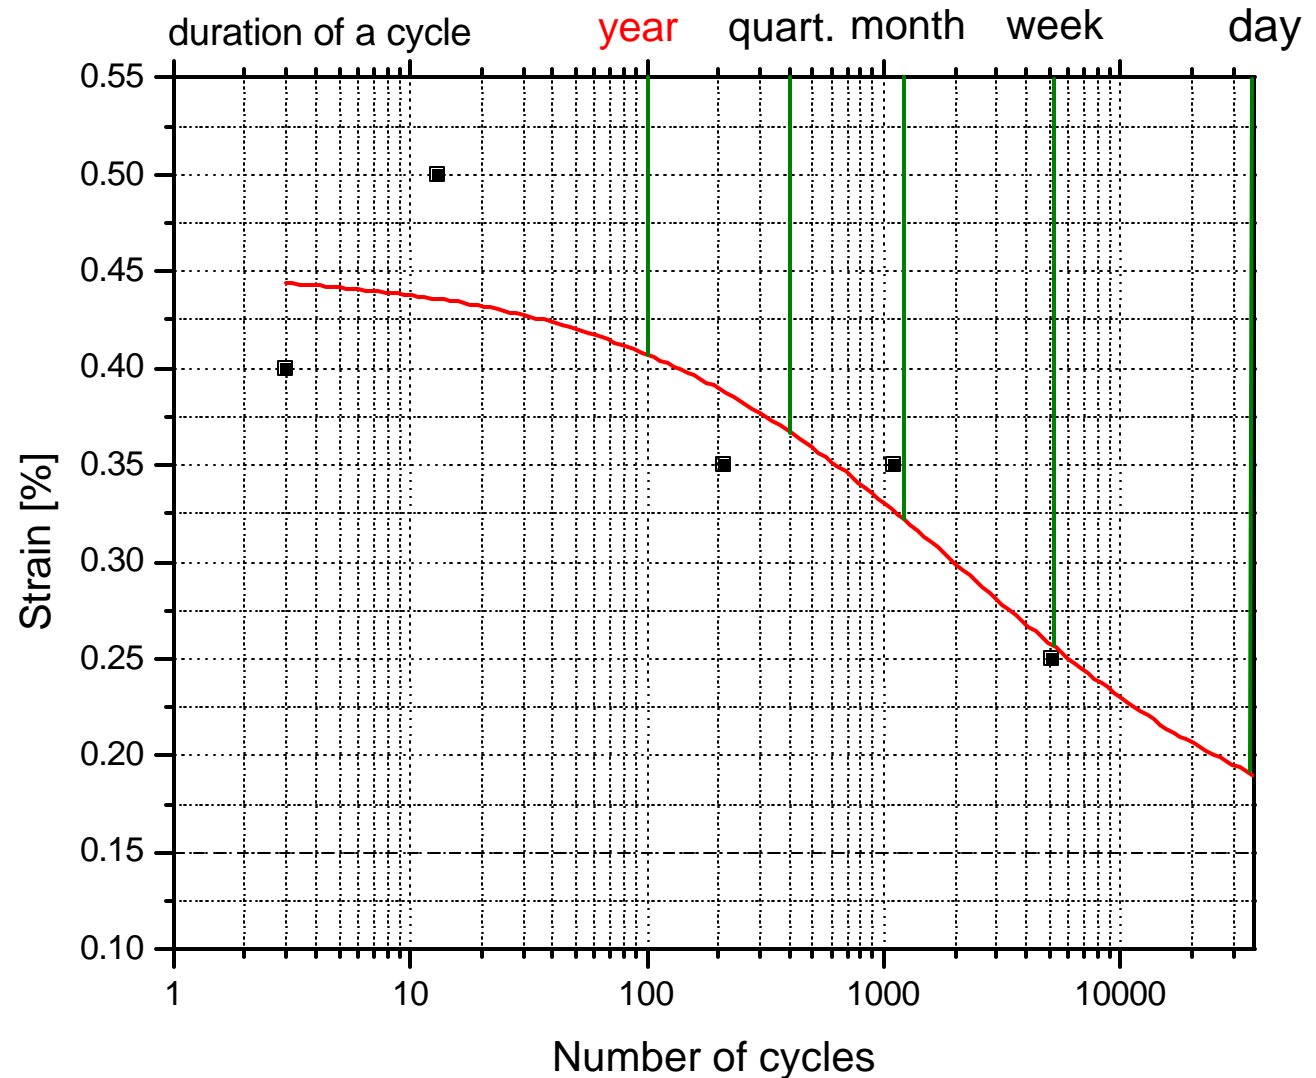

Diurnal variations  
at Malbork Castle, Poland

Seasonal changes  
at V&A Museum, London

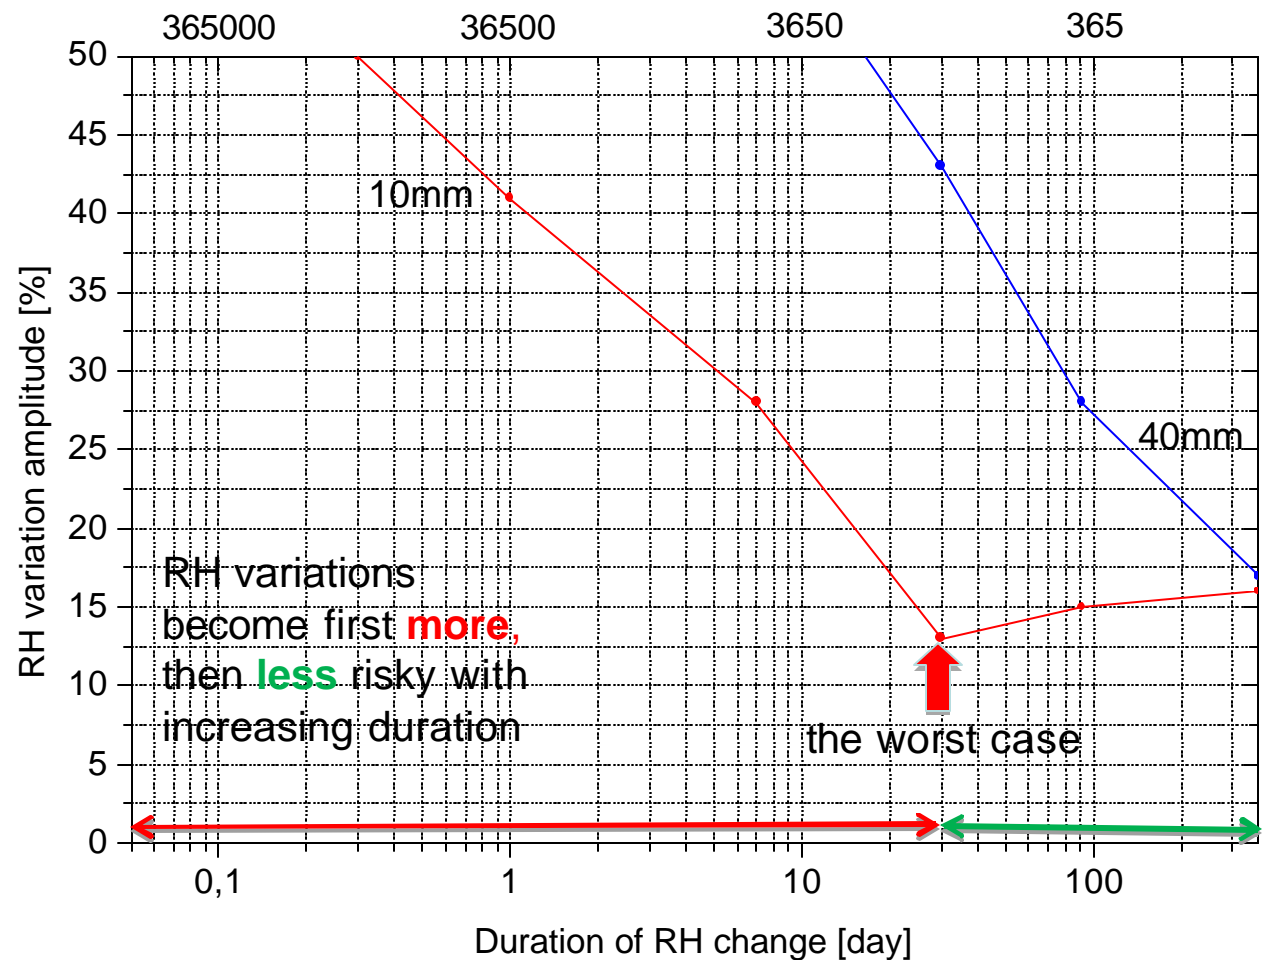

Over **100 years** wooden objects can endure larger strains if repeated less frequently. **Yearly** cycles give the maximum gain.

# Relationship between the **amplitude** of allowable RH variations and their **duration**

RH variations which will not cause damage of panels 10 or 40 mm thick during **100 years**

# Panel paintings undergo **deformation** (cupping)

---

Thin panels are subjected to a restraint by the applied gesso layer

*Christ blessing  
the children,*  
Lucas Cranach  
the Elder

lime panel  
**3-5 mm thick**

*Wawel Royal  
Castle, Krakow,  
Poland*

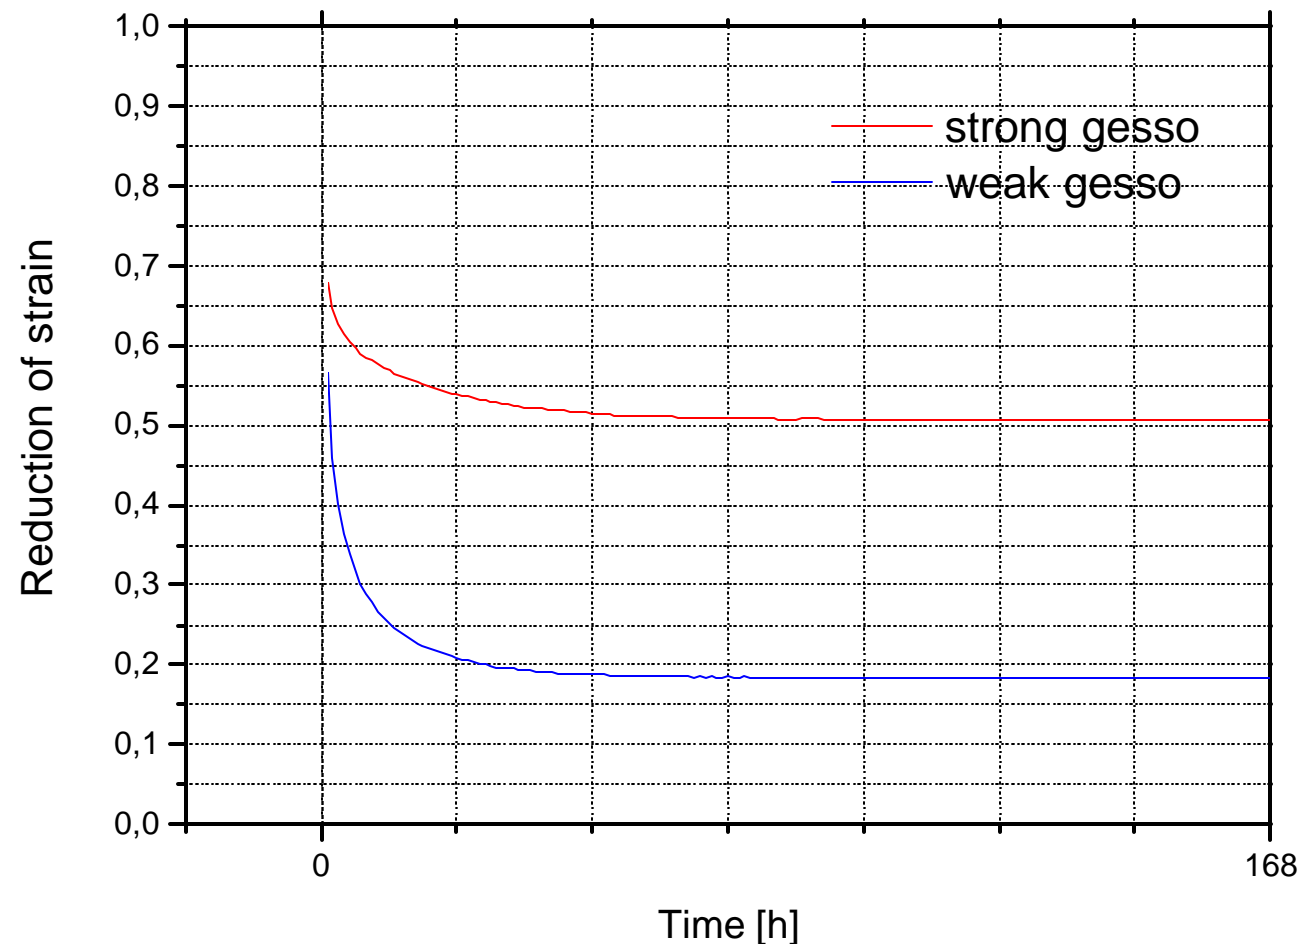

# Deformation **reduces strain** at the painted surface

---

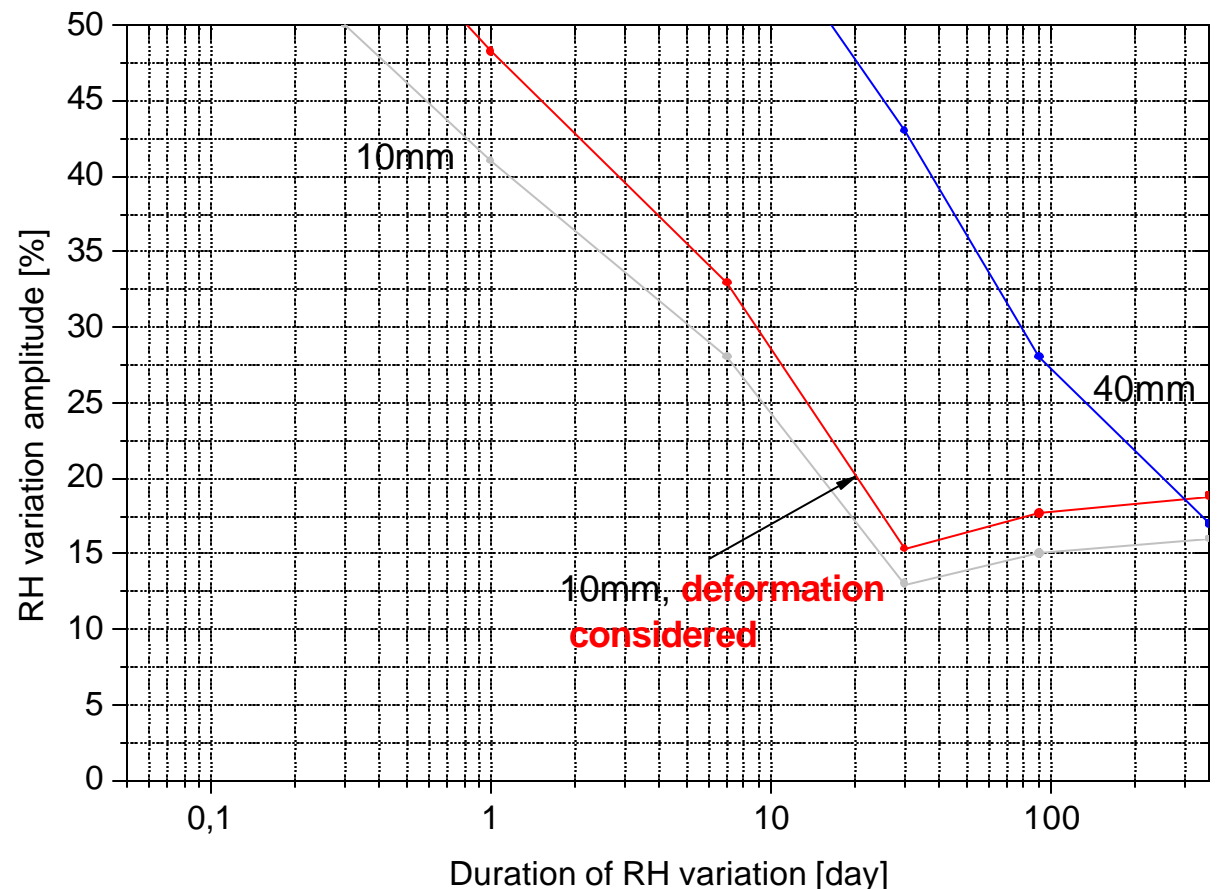

thickness of a panel 1 cm

thickness of the gesso layer 1 mm

# Relationship between the **amplitude** of allowable RH variations and their **duration**

RH variations which will not cause damage of panels 10 or 40 mm thick during **100 years**

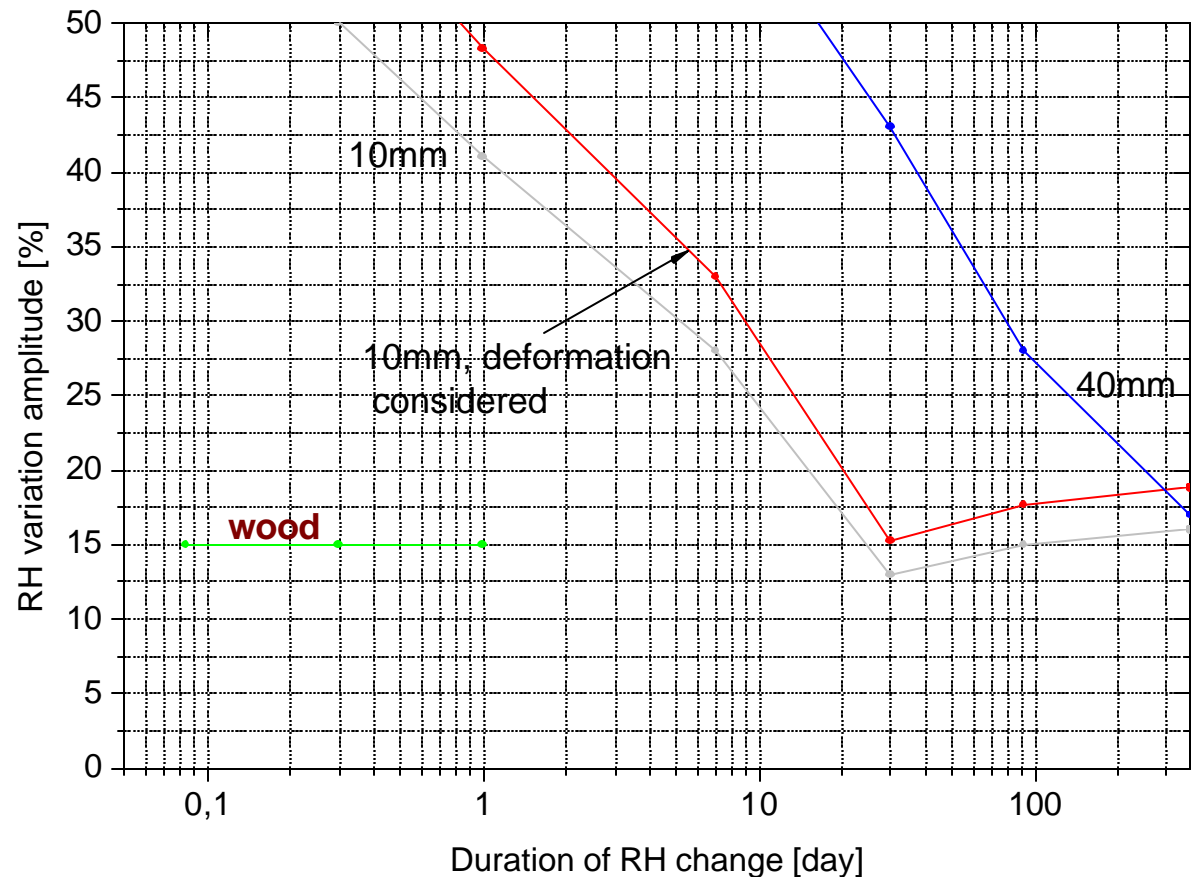

# Critical strain for wood – 0.5%

# Relationship between the **amplitude** of allowable RH variations and their **duration**

S. Jakiela, L. Bratasz, R. Kozlowski, *Wood Science and Technology*, 42, (2008), 21-37

# Relationship between the **amplitude** of allowable RH variations and their **duration**

B. Madson, *Forest Product Journal*, 25, 8 (1975), 48-53

# Allowable RH variations - conclusions

---

RH-induced wood movement initiating damage after 100 years corresponds to a relatively narrow band of  $\pm 15\%rh$  centred at 50%rh

... even if the effects reducing strain have been taken into account

# How does this compare to international specifications?

*Museums, Galleries, Archives and Libraries*, Chapter 21, ASHRAE Handbook  
– HVAC applications, ASHRAE - American Society of Heating, Refrigerating,  
and Air-Conditioning Engineers Inc. (2007)

Class of control	Short fluctuations	Seasonal adjustment in system set point	Collection risks
A	$\pm 5\%$	up 10%rh down 10% rh	small risk of mechanical damage to high- vulnerability artifacts, no risk to most artifacts
precision control or seasonal changes, not both	$\pm 10\%$	no change	
B	$\pm 10\%$	up 10%rh down 10% rh	moderate risk of mechanical damage to high-vulnerability artifacts, tiny risk to most artifacts
precision control and seasonal changes			

# Allowable RH variations - conclusions

---

Real-world RH variations in churches, historic buildings and many museums often exceed the  $\pm 15\%rh$  band

Therefore, the decorative layers are usually **extensively cracked**

# The network of **vertical cracks** in Leonardo's Mona Lisa

---

*Au coeur de La  
Joconde, Léonard  
de Vinci décodé*  
Gallimard and  
Musée du Louvre  
Editions (2006)

# The network of **vertical cracks** in Leonardo's Mona Lisa

Musée du Louvre  
Editions (2006)

Next step – a correction due to cracking should be estimated

---

What is the critical wood movement above which damage in **cracked** decorative layer appears?

- experimental approach similar to one presented but for specimens with **pre-cracked** decorative layer
- numerical simulations

# Going **beyond** the analysis of mechanical behaviour of painted wood

- analysis of **historic climate** - the acclimatisation or 'proofed-fluctuation' concept
- **direct tracing** non-recoverable micro-changes to objects to determine object-specific safe microclimates with a high precision
- attempts at a generalisation – '**population studies**'
